Rectangle method

From Wikipedia, the free encyclopedia

It has been suggested that this article or section be merged with *Riemann Integra*

This article **does not cite any references or sources**. Please help improve this
challenged and removed. *(December 2009)*

In mathematics, specifically in integral calculus, the **rectangle method** (also called the *midpoint* or *mid-ordinate ru*
rectangles whose heights are determined by the values of the function.

Specifically, the interval (a, b) over which the function is to be integrated is divided into N equal subintervals of len
or the middle of their top line lies on the graph of the function, with bases running along the x-axis. The approximatio
rectangles, giving the formula:

$$\int_a^b f(x)\,dx \approx h \sum_{n=0}^{N-1} f(x_n)$$

where $h = (b-a)/N$ and $x_n = a + nh$.

The formula for x_n above gives x_n for the Top-left corner approximation.

As N gets larger, this approximation gets more accurate. In fact, this computation is the spirit of the definition of the
integral of f on (a, b) if this Riemann integral is defined. Note that this is true regardless of which i' is used, howe
